IMMERSED MICROARRAYS IN WELLS

Priority Claim

This application claims priority on U.S. Provisional Application 60/463,563 filed on April 16, 2003. This application is incorporated herein in its entirety for all purposes.

Field of the Invention

The present invention relates to biological assays, more particularly to the packaging of biological assays.

Summary of the Invention

In one aspect of the invention, methods and systems for the construction and process
10 of a microarray plate are provided.

In one embodiment of the invention, a system for processing a microarray comprising
of a microarray plate, a hybridization plate, a plurality of washing plates, a plurality of
staining plates and a detection plates are used to process the microarray. The multiple
hybridization, washing, staining and detection plates used in this system can use clean
15 solutions during the process. Furthermore, the hybridization, washing, staining and detection
plates can be disposable.

In one embodiment of the invention, the microarray is immersed and assembled with
the hybridization plate. After the hybridization process, the microarray plate can be
immersed in a plurality of washing and staining plates, then transferred and assembled with
20 the detection plate to perform the scanning process.

In one embodiment of the application, a microarray plate comprises a plate; wherein
the plate has a plurality of support members and wherein the plate has features along the
borders for clamping; and a plurality of sensors. The sensors can be bonded to the end of the

support members for example with an adhesive, welding or by any means known in the art.

The bonding of the sensors to the end of the supporting members can be done with a UV curable and low-fluorescence adhesive. In a further embodiment of the invention, the sensors can be microarrays. The microarray plate can have features along the borders of the plate to assist with the clamping to the processing plates (i.e. the hybridization plate, detection plate, etc.)

In another embodiment of the invention, a hybridization plate comprises a plate with a plurality of wells. The plate is made of a material which can withstand the high temperatures (i.e. over 60°C) used during the hybridization process (i.e. polycarbonate, fused silica, etc.) The hybridization plate can be made with a sealing surface where the sealing surface can be an over-molded onto the hybridization plate. The sealing material can be of materials such as such as an elastomer. In a further embodiment, the hybridization plate can have features along the borders of the plate so as to assist with the clamping of the hybridization plate with the microarray plate.

In another embodiment of the invention, a detection plate comprises a plate with a plurality of wells. The detection plate is used during the scanning during the process of the microarray plate. The detection plate can have an optically clear window at the bottom of the wells which can be used to scan the microarray. The detection plate can be made of one solid molded material and low fluorescent (i.e. zeonor or zeonox). The detection plate can also have features along the borders to assist with the clamping and assembling of the microarray plate with the detection plate during the scanning process.

Brief Description of the Drawings

Figure 1 depicts an example of a microarray plate.

Figure 2A depicts is a hybridization plate.

Figure 2A depicts a detail of a hybrization plate with a sealing surface.

5 Figure 3 illustrates the assembly of a microarray plate with a hybridization plate and the location of a sealing surface.

Figure 4 depicts a detection plate.

Figure 5 depicts the assembly of a microarray plate with a detection plate.

Detailed Description of the Invention

10 The present invention has many preferred embodiments and relies on many patents, applications and other references for details known to those of the art. Therefore, when a patent, application, or other reference is cited or repeated below, it should be understood that it is incorporated by reference in its entirety for all purposes as well as for the proposition that is recited.

15 I. General

As used in this application, the singular form “a,” “an,” and “the” include plural references unless the context clearly dictates otherwise. For example, the term “an agent” includes a plurality of agents, including mixtures thereof.

20 An individual is not limited to a human being but may also be other organisms including but not limited to mammals, plants, bacteria, or cells derived from any of the above.

Throughout this disclosure, various aspects of this invention can be presented in a range format. It should be understood that the description in range format is merely for

convenience and brevity and should not be construed as an inflexible limitation on the scope of the invention. Accordingly, the description of a range should be considered to have specifically disclosed all the possible subranges as well as individual numerical values within that range. For example, description of a range such as from 1 to 6 should be considered to have specifically disclosed subranges such as from 1 to 3, from 1 to 4, from 1 to 5, from 2 to 4, from 2 to 6, from 3 to 6 etc., as well as individual numbers within that range, for example, 1, 2, 3, 4, 5, and 6. This applies regardless of the breadth of the range.

The practice of the present invention may employ, unless otherwise indicated, conventional techniques and descriptions of organic chemistry, polymer technology, molecular biology (including recombinant techniques), cell biology, biochemistry, and immunology, which are within the skill of the art. Such conventional techniques include polymer array synthesis, hybridization, ligation, and detection of hybridization using a label. Specific illustrations of suitable techniques can be had by reference to the example herein below. However, other equivalent conventional procedures can, of course, also be used.

Such conventional techniques and descriptions can be found in standard laboratory manuals such as Genome Analysis: A Laboratory Manual Series (Vols. I-IV), Using Antibodies: A Laboratory Manual, Cells: A Laboratory Manual, PCR Primer: A Laboratory Manual, and Molecular Cloning: A Laboratory Manual (all from Cold Spring Harbor Laboratory Press), Stryer, L. (1995) Biochemistry (4th Ed.) Freeman, New York, Gait, "Oligonucleotide Synthesis: A Practical Approach" 1984, IRL Press, London, Nelson and Cox (2000), Lehninger, Principles of Biochemistry 3rd Ed., W.H. Freeman Pub., New York, NY and Berg et al. (2002) Biochemistry, 5th Ed., W.H. Freeman Pub., New York, NY, all of which are herein incorporated in their entirety by reference for all purposes.

The present invention can employ solid substrates, including arrays in some preferred embodiments. Methods and techniques applicable to polymer (including protein) array synthesis have been described in U.S.S.N 09/536,841, WO 00/58516, U.S. Patents Nos. 5,143,854, 5,242,974, 5,252,743, 5,324,633, 5,384,261, 5,405,783, 5,424,186, 5,451,683, 5,482,867, 5,491,074, 5,527,681, 5,550,215, 5,571,639, 5,578,832, 5,593,839, 5,599,695, 5,624,711, 5,631,734, 5,795,716, 5,831,070, 5,837,832, 5,856,101, 5,858,659, 5,936,324, 5,968,740, 5,974,164, 5,981,185, 5,981,956, 6,025,601, 6,033,860, 6,040,193, 6,090,555, 6,136,269, 6,269,846 and 6,428,752, in PCT Applications Nos. PCT/US99/00730 (International Publication Number WO 99/36760) and PCT/US01/04285, which are all incorporated herein by reference in their entirety for all purposes.

Patents that describe synthesis techniques in specific embodiments include U.S. Patents Nos. 5,412,087, 6,147,205, 6,262,216, 6,310,189, 5,889,165, and 5,959,098. Nucleic acid arrays are described in many of the above patents, but the same techniques are applied to polypeptide arrays which are also described.

Nucleic acid arrays that are useful in the present invention include those that are commercially available from Affymetrix (Santa Clara, CA) under the brand name GeneChip®. Example arrays are shown on the website at affymetrix.com.

The present invention also contemplates many uses for polymers attached to solid substrates. These uses include gene expression monitoring, profiling, library screening, genotyping and diagnostics. Gene expression monitoring, and profiling methods are shown in U.S. Patents Nos. 5,800,992, 6,013,449, 6,020,135, 6,033,860, 6,040,138, 6,177,248 and 6,309,822. Genotyping and uses therefore are shown in USSN 60/319,253, 10/013,598, and U.S. Patents Nos. 5,856,092, 6,300,063, 5,858,659, 6,284,460, 6,361,947, 6,368,799 and 6,333,179.

Other uses are embodied in U.S. Patents Nos. 5,871,928, 5,902,723, 6,045,996, 5,541,061, and 6,197,506.

The present invention also contemplates sample preparation methods in certain preferred embodiments. Prior to or concurrent with genotyping, the genomic sample may be amplified by a variety of mechanisms, some of which may employ PCR. See, e.g., PCR Technology: Principles and Applications for DNA Amplification (Ed. H.A. Erlich, Freeman Press, NY, NY, 1992); PCR Protocols: A Guide to Methods and Applications (Eds. Innis, et al., Academic Press, San Diego, CA, 1990); Mattila et al., Nucleic Acids Res. 19, 4967 (1991); Eckert et al., PCR Methods and Applications 1, 17 (1991); PCR (Eds. McPherson et al., IRL Press, Oxford); and U.S. Patent Nos. 4,683,202, 4,683,195, 4,800,159 4,965,188, and 5,333,675, and each of which is incorporated herein by reference in their entireties for all purposes. The sample may be amplified on the array. See, for example, U.S. Patent No 6,300,070 and U.S. patent application 09/513,300, which are incorporated herein by reference.

Other suitable amplification methods include the ligase chain reaction (LCR) (e.g., Wu and Wallace, Genomics 4, 560 (1989), Landegren et al., Science 241, 1077 (1988) and Barringer et al. Gene 89:117 (1990)), transcription amplification (Kwoh et al., Proc. Natl. Acad. Sci. USA 86, 1173 (1989) and WO88/10315), self sustained sequence replication (Guatelli et al., Proc. Nat. Acad. Sci. USA, 87, 1874 (1990) and WO90/06995), selective amplification of target polynucleotide sequences (U.S. Patent No 6,410,276), consensus sequence primed polymerase chain reaction (CP-PCR) (U.S. Patent No 4,437,975), arbitrarily primed polymerase chain reaction (AP-PCR) (U.S. Patent No 5,413,909, 5,861,245) and nucleic acid based sequence amplification (NABSA). (See, US patents nos.

5,409,818, 5,554,517, and 6,063,603, each of which is incorporated herein by reference).

Other amplification methods that may be used are described in, U.S. Patent Nos. 5,242,794, 5,494,810, 4,988,617 and in USSN 09/854,317, each of which is incorporated herein by reference.

5 Additional methods of sample preparation and techniques for reducing the complexity of a nucleic sample are described in Dong et al., Genome Research 11, 1418 (2001), in U.S. Patent No 6,361,947, 6,391,592 and U.S. Patent application Nos. 09/916,135, 09/920,491, 09/910,292, and 10/013,598, which are incorporated herein by reference for all purposes.

Methods for conducting polynucleotide hybridization assays have been well
10 developed in the art. Hybridization assay procedures and conditions will vary depending on the application and are selected in accordance with the general binding methods known including those referred to in: Maniatis et al. Molecular Cloning: A Laboratory Manual (2nd Ed. Cold Spring Harbor, N.Y, 1989); Berger and Kimmel Methods in Enzymology, Vol. 152, Guide to Molecular Cloning Techniques (Academic Press, Inc., San Diego, CA, 1987);
15 Young and Davism, P.N.A.S, 80: 1194 (1983). Methods and apparatus for carrying out repeated and controlled hybridization reactions have been described in US patent 5,871,928, 5,874,219, 6,045,996 and 6,386,749, 6,391,623 each of which are incorporated herein by reference.

The present invention also contemplates signal detection of hybridization between
20 ligands in certain preferred embodiments. See U.S. Pat. Nos. 5,143,854, 5,578,832; 5,631,734; 5,834,758; 5,936,324; 5,981,956; 6,025,601; 6,141,096; 6,185,030; 6,201,639; 6,218,803; and 6,225,625, in U.S. Patent application 60/364,731 and in PCT Application

PCT/US99/06097 (published as WO99/47964), each of which also is hereby incorporated by reference in its entirety for all purposes.

Methods and apparatus for signal detection and processing of intensity data are disclosed in, for example, U.S. Patents Numbers 5,143,854, 5,547,839, 5,578,832, 5,631,734, 5,800,992, 5,834,758; 5,856,092, 5,902,723, 5,936,324, 5,981,956, 6,025,601, 6,090,555, 6,141,096, 6,185,030, 6,201,639; 6,218,803; and 6,225,625, in U.S. Patent application 60/364,731 and in PCT Application PCT/US99/06097 (published as WO99/47964), each of which also is hereby incorporated by reference in its entirety for all purposes.

The practice of the present invention may also employ conventional biology methods, software and systems. Computer software products of the invention typically include computer readable medium having computer-executable instructions for performing the logic steps of the method of the invention. Suitable computer readable medium include floppy disk, CD-ROM/DVD/DVD-ROM, hard-disk drive, flash memory, ROM/RAM, magnetic tapes and etc. The computer executable instructions may be written in a suitable computer language or combination of several languages. Basic computational biology methods are described in, e.g. Setubal and Meidanis et al., Introduction to Computational Biology Methods (PWS Publishing Company, Boston, 1997); Salzberg, Searles, Kasif, (Ed.), Computational Methods in Molecular Biology, (Elsevier, Amsterdam, 1998); Rashidi and Buehler, Bioinformatics Basics: Application in Biological Science and Medicine (CRC Press, London, 2000) and Ouelette and Bzevanis Bioinformatics: A Practical Guide for Analysis of Gene and Proteins (Wiley & Sons, Inc., 2nd ed., 2001).

The present invention may also make use of various computer program products and software for a variety of purposes, such as probe design, management of data, analysis, and

instrument operation. See, U.S. Patent Nos. 5,593,839, 5,795,716, 5,733,729, 5,974,164, 6,066,454, 6,090,555, 6,185,561, 6,188,783, 6,223,127, 6,229,911 and 6,308,170, which are incorporated herein by reference.

Additionally, the present invention may have preferred embodiments that include methods for providing genetic information over networks such as the Internet as shown in U.S. Patent applications 10/063,559, 60/349,546, 60/376,003, 60/394,574, 60/403,381.

II. Glossary

The following terms are intended to have the following general meanings as used herein.

Nucleic acids according to the present invention may include any polymer or oligomer of pyrimidine and purine bases, preferably cytosine (C), thymine (T), and uracil (U), and adenine (A) and guanine (G), respectively. See Albert L. Lehninger, PRINCIPLES OF BIOCHEMISTRY, at 793-800 (Worth Pub. 1982). Indeed, the present invention contemplates any deoxyribonucleotide, ribonucleotide or peptide nucleic acid component, and any chemical variants thereof, such as methylated, hydroxymethylated or glucosylated forms of these bases, and the like. The polymers or oligomers may be heterogeneous or homogeneous in composition, and may be isolated from naturally occurring sources or may be artificially or synthetically produced. In addition, the nucleic acids may be deoxyribonucleic acid (DNA) or ribonucleic acid (RNA), or a mixture thereof, and may exist permanently or transitionally in single-stranded or double-stranded form, including homoduplex, heteroduplex, and hybrid states.

An "oligonucleotide" or "polynucleotide" is a nucleic acid ranging from at least 2, preferable at least 8, and more preferably at least 20 nucleotides in length or a compound that specifically hybridizes to a polynucleotide. Polynucleotides of the present invention include sequences of deoxyribonucleic acid (DNA) or ribonucleic acid (RNA), which may be
5 isolated from natural sources, recombinantly produced or artificially synthesized and mimetics thereof. A further example of a polynucleotide of the present invention may be peptide nucleic acid (PNA) in which the constituent bases are joined by peptides bonds rather than phosphodiester linkage, as described in Nielsen et al., Science 254:1497-1500 (1991), Nielsen Curr. Opin. Biotechnol., 10:71-75 (1999). The invention also encompasses
10 situations in which there is a nontraditional base pairing such as Hoogsteen base pairing which has been identified in certain tRNA molecules and postulated to exist in a triple helix. "Polynucleotide" and "oligonucleotide" are used interchangeably in this application.

An "array" is an intentionally created collection of molecules which can be prepared either synthetically or biosynthetically. The molecules in the array can be identical or
15 different from each other. The array can assume a variety of formats, e.g., libraries of soluble molecules; libraries of compounds tethered to resin beads, silica chips, or other solid supports.

A nucleic acid library or array is an intentionally created collection of nucleic acids which can be prepared either synthetically or biosynthetically in a variety of different formats
20 (e.g., libraries of soluble molecules; and libraries of oligonucleotides tethered to resin beads, silica chips, or other solid supports). Additionally, the term "array" is meant to include those libraries of nucleic acids which can be prepared by spotting nucleic acids of essentially any length (e.g., from 1 to about 1000 nucleotide monomers in length) onto a substrate. The term

“nucleic acid” as used herein refers to a polymeric form of nucleotides of any length, either ribonucleotides, deoxyribonucleotides or peptide nucleic acids (PNAs), that comprise purine and pyrimidine bases, or other natural, chemically or biochemically modified, non-natural, or derivatized nucleotide bases (see, e.g., U.S. Patent No. 6,156, 501, incorporated herein by
5 reference). The backbone of the polynucleotide can comprise sugars and phosphate groups, as may typically be found in RNA or DNA, or modified or substituted sugar or phosphate groups. A polynucleotide may comprise modified nucleotides, such as methylated nucleotides and nucleotide analogs. The sequence of nucleotides may be interrupted by non-nucleotide components. Thus the terms nucleoside, nucleotide, deoxynucleoside and
10 deoxynucleotide generally include analogs such as those described herein. These analogs are those molecules having some structural features in common with a naturally occurring nucleoside or nucleotide such that when incorporated into a nucleic acid or oligonucleotide sequence, they allow hybridization with a naturally occurring nucleic acid sequence in solution. Typically, these analogs are derived from naturally occurring nucleosides and
15 nucleotides by replacing and/or modifying the base, the ribose or the phosphodiester moiety. The changes can be tailor made to stabilize or destabilize hybrid formation or enhance the specificity of hybridization with a complementary nucleic acid sequence as desired.

"Solid support", "support", and "substrate" are used interchangeably and refer to a material or group of materials having a rigid or semi-rigid surface or surfaces. In many
20 embodiments, at least one surface of the solid support will be substantially flat, although in some embodiments it may be desirable to physically separate synthesis regions for different compounds with, for example, wells, raised regions, pins, etched trenches, or the like.

According to other embodiments, the solid support(s) will take the form of beads, resins, gels, microspheres, or other geometric configurations.

Combinatorial Synthesis Strategy: A combinatorial synthesis strategy is an ordered strategy for parallel synthesis of diverse polymer sequences by sequential addition of reagents which may be represented by a reactant matrix and a switch matrix, the product of which is a product matrix. A reactant matrix is a l column by m row matrix of the building blocks to be added. The switch matrix is all or a subset of the binary numbers, preferably ordered, between l and m arranged in columns. A "binary strategy" is one in which at least two successive steps illuminate a portion, often half, of a region of interest on the substrate. In a binary synthesis strategy, all possible compounds which can be formed from an ordered set of reactants are formed. In most preferred embodiments, binary synthesis refers to a synthesis strategy which also factors a previous addition step. For example, a strategy in which a switch matrix for a masking strategy halves regions that were previously illuminated, illuminating about half of the previously illuminated region and protecting the remaining half (while also protecting about half of previously protected regions and illuminating about half of previously protected regions). It will be recognized that binary rounds may be interspersed with non-binary rounds and that only a portion of a substrate may be subjected to a binary scheme. A combinatorial "masking" strategy is a synthesis which uses light or other spatially selective deprotecting or activating agents to remove protecting groups from materials for addition of other materials such as amino acids. See, e.g., U.S. Patent No. 5,143,854.

Monomer: refers to any member of the set of molecules that can be joined together to form an oligomer or polymer. The set of monomers useful in the present invention includes, but is not restricted to, for the example of (poly)peptide synthesis, the set of L-amino acids,

D-amino acids, or synthetic amino acids. As used herein, "monomer" refers to any member of a basis set for synthesis of an oligomer. For example, dimers of L-amino acids form a basis set of 400 "monomers" for synthesis of polypeptides. Different basis sets of monomers may be used at successive steps in the synthesis of a polymer. The term "monomer" also
5 refers to a chemical subunit that can be combined with a different chemical subunit to form a compound larger than either subunit alone.

Biopolymer or biological polymer: is intended to mean repeating units of biological or chemical moieties. Representative biopolymers include, but are not limited to, nucleic acids, oligonucleotides, amino acids, proteins, peptides, hormones, oligosaccharides, lipids,
10 glycolipids, lipopolysaccharides, phospholipids, synthetic analogues of the foregoing, including, but not limited to, inverted nucleotides, peptide nucleic acids, Meta-DNA, and combinations of the above. "Biopolymer synthesis" is intended to encompass the synthetic production, both organic and inorganic, of a biopolymer.

Related to a biopolymer is a "biomonomer" which is intended to mean a single unit of
15 biopolymer, or a single unit which is not part of a biopolymer. Thus, for example, a nucleotide is a biomonomer within an oligonucleotide biopolymer, and an amino acid is a biomonomer within a protein or peptide biopolymer; avidin, biotin, antibodies, antibody fragments, etc., for example, are also biomonomers. Initiation Biomonomer: or "initiator biomonomer" is meant to indicate the first biomonomer which is covalently attached via
20 reactive nucleophiles to the surface of the polymer, or the first biomonomer which is attached to a linker or spacer arm attached to the polymer, the linker or spacer arm being attached to the polymer via reactive nucleophiles.

Complementary: Refers to the hybridization or base pairing between nucleotides or nucleic acids, such as, for instance, between the two strands of a double stranded DNA molecule or between an oligonucleotide primer and a primer binding site on a single stranded nucleic acid to be sequenced or amplified. Complementary nucleotides are, generally, A and T (or A and U), or C and G. Two single stranded RNA or DNA molecules are said to be complementary when the nucleotides of one strand, optimally aligned and compared and with appropriate nucleotide insertions or deletions, pair with at least about 80% of the nucleotides of the other strand, usually at least about 90% to 95%, and more preferably from about 98 to 100%. Alternatively, complementarity exists when an RNA or DNA strand will hybridize under selective hybridization conditions to its complement. Typically, selective hybridization will occur when there is at least about 65% complementary over a stretch of at least 14 to 25 nucleotides, preferably at least about 75%, more preferably at least about 90% complementary. See, M. Kanehisa Nucleic Acids Res. 12:203 (1984), incorporated herein by reference.

The term “hybridization” refers to the process in which two single-stranded polynucleotides bind non-covalently to form a stable double-stranded polynucleotide. The term “hybridization” may also refer to triple-stranded hybridization. The resulting (usually) double-stranded polynucleotide is a “hybrid.” The proportion of the population of polynucleotides that forms stable hybrids is referred to herein as the “degree of hybridization”.

Hybridization conditions will typically include salt concentrations of less than about 1M, more usually less than about 500 mM and less than about 200 mM. Hybridization temperatures can be as low as 5°C, but are typically greater than 22°C, more typically greater

than about 30°C, and preferably in excess of about 37°C. Hybridizations are usually performed under stringent conditions, i.e. conditions under which a probe will hybridize to its target subsequence. Stringent conditions are sequence-dependent and are different in different circumstances. Longer fragments may require higher hybridization temperatures for specific hybridization. As other factors may affect the stringency of hybridization, including base composition and length of the complementary strands, presence of organic solvents and extent of base mismatching, the combination of parameters is more important than the absolute measure of any one alone. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (T_m) from the specific sequence at a defined ionic strength and pH. The T_m is the temperature (under defined ionic strength, pH and nucleic acid composition) at which 50% of the probes complementary to the target sequence hybridize to the target sequence at equilibrium.

Typically, stringent conditions include salt concentration of at least 0.01 M to no more than 1 M Na ion concentration (or other salts) at a pH 7.0 to 8.3 and a temperature of at least 25°C. For example, conditions of 5X SSPE (750 mM NaCl, 50 mM NaPhosphate, 5 mM EDTA, pH 7.4) and a temperature of 25-30°C are suitable for allele-specific probe hybridizations. For stringent conditions, see for example, Sambrook, Fritsche and Maniatis. "Molecular Cloning A laboratory Manual" 2nd Ed. Cold Spring Harbor Press (1989) and Anderson "Nucleic Acid Hybridization" 1st Ed., BIOS Scientific Publishers Limited (1999), which are hereby incorporated by reference in its entirety for all purposes above.

Hybridization probes are nucleic acids (such as oligonucleotides) capable of binding in a base-specific manner to a complementary strand of nucleic acid. Such probes include peptide nucleic acids, as described in Nielsen et al., Science 254:1497-1500 (1991), Nielsen

Curr. Opin. Biotechnol., 10:71-75 (1999) and other nucleic acid analogs and nucleic acid mimetics. See US Patent No. 6,156,501.

Probe: A probe is a molecule that can be recognized by a particular target. In some embodiments, a probe can be surface immobilized. Examples of probes that can be investigated by this invention include, but are not restricted to, agonists and antagonists for cell membrane receptors, toxins and venoms, viral epitopes, hormones (e.g., opioid peptides, steroids, etc.), hormone receptors, peptides, enzymes, enzyme substrates, cofactors, drugs, lectins, sugars, oligonucleotides, nucleic acids, oligosaccharides, proteins, and monoclonal antibodies.

Target: A molecule that has an affinity for a given probe. Targets may be naturally-occurring or man-made molecules. Also, they can be employed in their unaltered state or as aggregates with other species. Targets may be attached, covalently or noncovalently, to a binding member, either directly or via a specific binding substance. Examples of targets which can be employed by this invention include, but are not restricted to, antibodies, cell membrane receptors, monoclonal antibodies and antisera reactive with specific antigenic determinants (such as on viruses, cells or other materials), drugs, oligonucleotides, nucleic acids, peptides, cofactors, lectins, sugars, polysaccharides, cells, cellular membranes, and organelles. Targets are sometimes referred to in the art as anti-probes. As the term targets is used herein, no difference in meaning is intended. A "Probe Target Pair" is formed when two macromolecules have combined through molecular recognition to form a complex.

Ligand: A ligand is a molecule that is recognized by a particular receptor. The agent bound by or reacting with a receptor is called a "ligand," a term which is definitionally meaningful only in terms of its counterpart receptor. The term "ligand" does not imply any

particular molecular size or other structural or compositional feature other than that the substance in question is capable of binding or otherwise interacting with the receptor. Also, a ligand may serve either as the natural ligand to which the receptor binds, or as a functional analogue that may act as an agonist or antagonist. Examples of ligands that can be

5 investigated by this invention include, but are not restricted to, agonists and antagonists for cell membrane receptors, toxins and venoms, viral epitopes, hormones (e.g., opiates, steroids, etc.), hormone receptors, peptides, enzymes, enzyme substrates, substrate analogs, transition state analogs, cofactors, drugs, proteins, and antibodies.

Receptor: A molecule that has an affinity for a given ligand. Receptors may be

10 naturally-occurring or manmade molecules. Also, they can be employed in their unaltered state or as aggregates with other species. Receptors may be attached, covalently or noncovalently, to a binding member, either directly or via a specific binding substance. Examples of receptors which can be employed by this invention include, but are not restricted to, antibodies, cell membrane receptors, monoclonal antibodies and antisera

15 reactive with specific antigenic determinants (such as on viruses, cells or other materials), drugs, polynucleotides, nucleic acids, peptides, cofactors, lectins, sugars, polysaccharides, cells, cellular membranes, and organelles. Receptors are sometimes referred to in the art as anti-ligands. As the term receptors is used herein, no difference in meaning is intended. A "Ligand Receptor Pair" is formed when two macromolecules have combined through

20 molecular recognition to form a complex. Other examples of receptors which can be investigated by this invention include but are not restricted to those molecules shown in U.S. Patent No. 5,143,854, which is hereby incorporated by reference in its entirety.

Effective amount refers to an amount sufficient to induce a desired result.

mRNA or mRNA transcripts: as used herein, include, but not limited to pre-mRNA transcript(s), transcript processing intermediates, mature mRNA(s) ready for translation and transcripts of the gene or genes, or nucleic acids derived from the mRNA transcript(s).

Transcript processing may include splicing, editing and degradation. As used herein, a

5 nucleic acid derived from an mRNA transcript refers to a nucleic acid for whose synthesis the mRNA transcript or a subsequence thereof has ultimately served as a template. Thus, a cDNA reverse transcribed from an mRNA, a cRNA transcribed from that cDNA, a DNA amplified from the cDNA, an RNA transcribed from the amplified DNA, etc., are all derived from the mRNA transcript and detection of such derived products is indicative of the
10 presence and/or abundance of the original transcript in a sample. Thus, mRNA derived samples include, but are not limited to, mRNA transcripts of the gene or genes, cDNA reverse transcribed from the mRNA, cRNA transcribed from the cDNA, DNA amplified from the genes, RNA transcribed from amplified DNA, and the like.

A fragment, segment, or DNA segment refers to a portion of a larger DNA
15 polynucleotide or DNA. A polynucleotide, for example, can be broken up, or fragmented into, a plurality of segments. Various methods of fragmenting nucleic acid are well known in the art. These methods may be, for example, either chemical or physical in nature. Chemical fragmentation may include partial degradation with a DNase; partial depurination with acid; the use of restriction enzymes; intron-encoded endonucleases; DNA-based cleavage methods,
20 such as triplex and hybrid formation methods, that rely on the specific hybridization of a nucleic acid segment to localize a cleavage agent to a specific location in the nucleic acid molecule; or other enzymes or compounds which cleave DNA at known or unknown locations. Physical fragmentation methods may involve subjecting the DNA to a high shear

rate. High shear rates may be produced, for example, by moving DNA through a chamber or channel with pits or spikes, or forcing the DNA sample through a restricted size flow passage, e.g., an aperture having a cross sectional dimension in the micron or submicron scale. Other physical methods include sonication and nebulization. Combinations of physical and chemical fragmentation methods may likewise be employed such as fragmentation by heat and ion-mediated hydrolysis. See for example, Sambrook et al., "Molecular Cloning: A Laboratory Manual," 3rd Ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (2001) ("Sambrook et al.") which is incorporated herein by reference for all purposes. These methods can be optimized to digest a nucleic acid into fragments of a selected size range. Useful size ranges may be from 100, 200, 400, 700 or 1000 to 500, 800, 1500, 2000, 4000 or 10,000 base pairs. However, larger size ranges such as 4000, 10,000 or 20,000 to 10,000, 20,000 or 500,000 base pairs may also be useful. See, e.g., Dong et al., Genome Research 11, 1418 (2001), in U.S. Patent No 6,361,947, 6,391,592, incorporated herein by reference.

A primer is a single-stranded oligonucleotide capable of acting as a point of initiation for template-directed DNA synthesis under suitable conditions e.g., buffer and temperature, in the presence of four different nucleoside triphosphates and an agent for polymerization, such as, for example, DNA or RNA polymerase or reverse transcriptase. The length of the primer, in any given case, depends on, for example, the intended use of the primer, and generally ranges from 15 to 30 nucleotides. Short primer molecules generally require cooler temperatures to form sufficiently stable hybrid complexes with the template. A primer need not reflect the exact sequence of the template but must be sufficiently complementary to hybridize with such template. The primer site is the area of the template to which a primer

hybridizes. The primer pair is a set of primers including a 5' upstream primer that hybridizes with the 5' end of the sequence to be amplified and a 3' downstream primer that hybridizes with the complement of the 3' end of the sequence to be amplified.

A genome is all the genetic material of an organism. In some instances, the term
5 genome may refer to the chromosomal DNA. Genome may be multichromosomal such that the DNA is cellularly distributed among a plurality of individual chromosomes. For example, in human there are 22 pairs of chromosomes plus a gender associated XX or XY pair. DNA derived from the genetic material in the chromosomes of a particular organism is genomic DNA. The term genome may also refer to genetic materials from organisms that do
10 not have chromosomal structure. In addition, the term genome may refer to mitochondria DNA. A genomic library is a collection of DNA fragments represents the whole or a portion of a genome. Frequently, a genomic library is a collection of clones made from a set of randomly generated, sometimes overlapping DNA fragments representing the entire genome or a portion of the genome of an organism.

15 An allele refers to one specific form of a genetic sequence (such as a gene) within a cell or within a population, the specific form differing from other forms of the same gene in the sequence of at least one, and frequently more than one, variant sites within the sequence of the gene. The sequences at these variant sites that differ between different alleles are termed "variances", "polymorphisms", or "mutations".

20 At each autosomal specific chromosomal location or "locus" an individual possesses two alleles, one inherited from the father and one from the mother. An individual is "heterozygous" at a locus if it has two different alleles at that locus. An individual is "homozygous" at a locus if it has two identical alleles at that locus.

Polymorphism refers to the occurrence of two or more genetically determined alternative sequences or alleles in a population. A polymorphic marker or site is the locus at which divergence occurs. Preferred markers have at least two alleles, each occurring at frequency of greater than 1%, and more preferably greater than 10% or 20% of a selected population. A polymorphism may comprise one or more base changes, an insertion, a repeat, or a deletion. A polymorphic locus may be as small as one base pair. Polymorphic markers include restriction fragment length polymorphisms, variable number of tandem repeats (VNTR's), hypervariable regions, minisatellites, dinucleotide repeats, trinucleotide repeats, tetranucleotide repeats, simple sequence repeats, and insertion elements such as Alu. The first identified allelic form is arbitrarily designated as the reference form and other allelic forms are designated as alternative or variant alleles. The allelic form occurring most frequently in a selected population is sometimes referred to as the wildtype form. Diploid organisms may be homozygous or heterozygous for allelic forms. A diallelic polymorphism has two forms. A triallelic polymorphism has three forms. Single nucleotide polymorphisms (SNPs) are included in polymorphisms.

Single nucleotide polymorphism (SNPs) are positions at which two alternative bases occur at appreciable frequency ($>1\%$) in the human population, and are the most common type of human genetic variation. The site is usually preceded by and followed by highly conserved sequences of the allele (e.g., sequences that vary in less than 1/100 or 1/1000 members of the populations). A single nucleotide polymorphism usually arises due to substitution of one nucleotide for another at the polymorphic site. A transition is the replacement of one purine by another purine or one pyrimidine by another pyrimidine. A transversion is the replacement of a purine by a pyrimidine or vice versa. Single nucleotide

polymorphisms can also arise from a deletion of a nucleotide or an insertion of a nucleotide relative to a reference allele.

Genotyping refers to the determination of the genetic information an individual carries at one or more positions in the genome. For example, genotyping may comprise the
5 determination of which allele or alleles an individual carries for a single SNP or the determination of which allele or alleles an individual carries for a plurality of SNPs. A genotype may be the identity of the alleles present in an individual at one or more polymorphic sites.

Linkage disequilibrium or allelic association means the preferential association of a
10 particular allele or genetic marker with a specific allele, or genetic marker at a nearby chromosomal location more frequently than expected by chance for any particular allele frequency in the population. For example, if locus X has alleles a and b, which occur equally frequently, and linked locus Y has alleles c and d, which occur equally frequently, one would expect the combination ac to occur with a frequency of 0.25. If ac occurs more frequently,
15 then alleles a and c are in linkage disequilibrium. Linkage disequilibrium may result from natural selection of certain combination of alleles or because an allele has been introduced into a population too recently to have reached equilibrium with linked alleles. A marker in linkage disequilibrium can be particularly useful in detecting susceptibility to disease (or other phenotype) notwithstanding that the marker does not cause the disease. For example, a
20 marker (X) that is not itself a causative element of a disease, but which is in linkage disequilibrium with a gene (including regulatory sequences) (Y) that is a causative element of a phenotype, can be detected to indicate susceptibility to the disease in circumstances in which the gene Y may not have been identified or may not be readily detectable.

III. Immersion Array Plates for Interchangeable Microtiter Well Plates

In one aspect of the invention, methods and apparatus for packaging microarray are provided. The following describes the design, materials, manufacturing processes and application protocols used for processing a microarray plate. The attached drawings illustrate
5 some of the embodiments of this array package design.

a) Design:

In one embodiment of the invention, the system for processing microarray plates comprises the use of various plates such as an array plate, a hybridization plate, a washing
10 plate, a staining plate and a detection plate.

i) The array plate, as depicted in Figure 1, is comprised of plate (101) wherein the plate has a plurality of supporting members (102) which can be in for example pegs, projecting from one side of the plate (i.e. 96 pegs). The array plate further comprising a
15 plurality of sensors wherein the sensors can be microarrays (104); wherein the sensors are attached to the end on the supporting members. In one embodiment of the invention, the sensors are attached to the plate with a low-fluorescent adhesive or by welding. The array plate can be made of any material which can withstand high temperatures for hybridization and that can be stored in cold temperatures for storage (i.e. cyrolite, Hi-Lo acrylic, etc.). In
20 one embodiment of the application, the sensors should be attached to the supporting members substantially flat with regard to the surface of the supporting member.

ii) The hybridization plate, as depicted in Figure 2 A, is designed to minimize fluidic volume introduced during hybridization as well as to minimize the depth spacing between the

well bottom and the array surface when the pegs of the array plate are inserted. In one embodiment of the invention, the hybridization plate is a plate (201) with a plurality of wells (202) that has features (203) along the borders of the plate which assist in the clamping and assembling of the array plate with the hybridization plate for the hybridization process. The hybridization plate is made of any material that can sustain high temperatures such as a high temperature molded plastic material (i.e. polycarbonate, polypropylene, etc.). As depicted in Figure 2 B, in a further embodiment of the invention, the hybridization plate (201) comprises a sealing surface (204) such as an elastomeric seal (204) between the microarray plate (101) and the hybridization wells (202) when the hybridization plate and microarray plate are assembled for the hybridization process to create the hermetic seal necessary for high temperature incubation. The sealing surface (204) can be made of any material known in the art such as an elastomeric over-mold seal. Typically the current well plates must be sealed with heat transferred films before any incubation or thermal cycling steps and pierced before aspirating any fluids from the wells. The use of this integrated seal onto the design hybridization plate also facilitates separation when the microarray plate assembly is removed from incubation. The design of the wells of the hybridization combined with the design of the supporting members of the microarray plate assists in reducing hybridization target volumes thus minimizing cost for processing the microarrays plates. In a further embodiment of the invention, the hybridization plate is suitable for chemiluminescence.

ii) The detection plate, which is used for processing the microarray plate during the scanning process, as illustrated in Figure 4, is a plate (401) with wells (403) designed to receive the microarray plate. The detection plate comprises a window of optically clear and

low-fluorescence material (404) such as fused silica, zeonor (zionex), etc. After the hybridization process, the microarray plate is transferred to the scanning plate. In an embodiment of the invention, the detection plate has features along the border (402) of the plate for assembly of the microarray plate with the detection plate. The optically clear window must be transparent and distortion free for purposes of imaging the surface of the microarrays. This material must also be non-fluorescent in order to minimize the background signal level and allow detection of low level signals from low intensity features of the probe array.

With this optically clear window of the detection plate, the immersed microarrays can be imaged and scanned using an array plate scanning instrument. The use of this multi-plastic molded design, the hybridization and detection plates can be produced at very low cost. In addition the design allows for flexibility to change the thickness of the optically clear window material to enhance image resolution of the microarray.

b) Materials:

There are several areas of this design that require special material capabilities. The non-fluorescent adhesive, the optically clear molded plastic material and the high temperature molded plastic materials for hybridization.

For this application, an adhesive is used to bond the microarrays to a plastic surface. Because the back surface (non-probe side) of the microarray is the bonding surface, the adhesive must be low-fluorescent at the working emission wavelengths of the hybridized, labeled probe arrays.

The hybridization well plate is typically used for the high temperature incubation and

high stringency wash steps of the array hybridization protocol. With this array plate concept the well plate can be produced with higher temperature plastics to enable hybridization conditions at temperatures in excess of 60°C.

5 c) Manufacturing Processes:

The design of this array plate lends itself to some potential high speed manufacturing processes. One concept is described here and is based on some established automation processes available.

10 The microarrays are typically transferred from the dicing film frame to a waffle pack via a high-speed “pick and place” instrument. In one embodiment of the invention, the wafer pack can be designed with pockets for example, located in a 9mm and 8x12 well layout of a 96 well format. Therefore, the transferred microarrays will be positioned with the probe side facing down in the waffle pack.

15 Following this, a plate with a plurality of support members or pegs can be pressed (or stamped) onto a pad surface which is coated with wet, uncured adhesive. Then the plate can be pressed onto the microarrays located in the waffle pack. This step is similar to an ink-stamping process used to transfer stamp patterns to a surface.

20 In one embodiment of the invention, the waffle pack can be designed with openings at the bottom of each pocket with a UV illumination source and a vacuum plenum chamber below to enable the waffle pack to hold the microarrays in position when the plate is pressed on top of the microarrays so as to create a microarray plate. Once the microarray plate is pressed into position, a UV light source is turned on to cure the adhesive. When the adhesive is cured, the microarray plate can be removed with the microarrays permanently bonded.

This process takes advantage of a multiple array format to assemble a plurality of microarrays, such as 96 microarrays, simultaneously in order to achieve high speed manufacturing.

5 d) Automated Assay Protocol:

The concept of using separate well plates for hybridization (and high temperature washing) and scanning enables higher efficiency washes and cleaner images when executing the protocol. In one embodiment of the invention, all three components in the kit (a hybridization plate, a washing tray, staining plate and a scanning tray) are disposable so
10 durability and cleanliness is not a requirement beyond its single use. However, since the critical process steps are performed in separate wells, contamination during sequential steps is minimized or eliminated. In addition the transfer of the microarray plates between steps should facilitate more efficient cleaning of the arrays.

The hybridization and high temperature washes are performed in the wells of these
15 plates which are designed to be assembled with the microarray plate. In order to minimize the fluidic volume of sample used during hybridization, the microarray plate is designed to minimize the spacing between the immersed array and the well bottom.

Normal washing that does not require high temperature incubation, since wash plates will work at a maximum temperature of 50°C, can be done in standard deep well plates
20 which are also very economical in price since they are commercially available. These commercially available well plates have very large size wells for standard DI water or buffer solutions. Following hybridization and any other steps requiring rinsing or washing, the microarray plates can be immersed into these deep well plates for cleaning. Since the wash

fluid volume is large, the cleaning process is more efficient and fewer wash steps would be required, thus saving further process time.

When the array plate has completed the hybridization, labeling and washing steps, it can finally be immersed into the virgin scanning plate with clean buffer for scanning.

5 The additional advantage of this array plate concept is the ability to implement the same protocol manually by a laboratory technician instead of an automated High Throughput System (HTS) liquid handling instrument. With this interchangeable well plate concept, it could be possible for a single laboratory technician to process for example 96 arrays through the hybridization protocol in approximately the same time to process a few cartridges with
10 the current available tools.

It is understood that any person skilled in the art could understand that there is not a minimum length for the supporting members of the microarray plate described in the present invention. However, it is inherently understood that there is a practical minimum length. A
15 longer supporting member may allow simpler washing and staining as it can be immersed deeper.

It is also understood by any person skilled in the art that there are not limitations as to the size of the sensors attached to the supporting members of the current invention. For example a 1mm by 1mm sensor can be mounted on the supporting members. However, the
20 sensors can be smaller.

In the present invention, a hybridization volume for volume for example for 6.3mm by 6.3mm sensors can be designed to be about 12ul. However, there are no design constraints that would prevent a smaller volume. It is also understood by any person skilled

in the art, that the detection plate described in the present invention is not volume sensitive. Buffer is used as a coupling fluid between the sensors and the bottom of the detection plate, and its total volume is incidental. However, the distance from sensors to the outside surface of the detection plate may need to be kept very small if the scanner objective lens has a short
5 focal length.

It is further understood by any person skilled in the art, that the transparent window of the detection plate of the present application has a low fluoresce background. In one example, a galvo scanner with no detection plates has a background of 7 counts. The detection plate has a total fluorescence background of 14 counts. The total galvo signal is
10 about 65,000 counts. A minimum acceptable fluorescence background for the window of the detection plate has not been established.

United States Patent Applications 10/325,171 filed December 19, 2002; 10/428,626 filed on May 2, 1003; 10/456,370 filed on June 6, 2003; and 10/738,535 filed on December 16, 2003 teach different aspects of constructing microarray plates, these applications are
15 incorporated in their entirety for all purposes.

It is to be understood that the description is intended to be illustrative and not restrictive. Many variations of the invention will be apparent to those of skill in the art upon reviewing the above description. All cited references, including patent and non-patent literature, are incorporated herewith by reference in their entirety for all purposes.
